

Step 2: Find AM's IP address

Interestingly enough, this is the simplest step. I logged on to AM, went to the terminal, and typed `hostname -I` to get AM's IP address. However, I wanted a better breakdown of both IPv4 and IPv6 IP addresses, so I typed `ip a`. From my understanding of these two different commands, `hostname -I` is good to quickly show you your IP address (IPv4 only), where as `ip a` or `ip addr` will show you both IPv4 and 6, and other things about the network.

Now that I have an IP address I can work with, I can move on to the next step in the lab.
